

# From NanoBob to RIQS: Towards the future Quantum Internet

2024-11-15 – Workshop distribution sécurisée du temps et systèmes spatiaux – Erik Kerstel

# The Dream: A global Quantum Information Network

The quantum internet has arrived (and it hasn't), *Nature* **554**, 289 (2018)

On-demand entanglement could lead to scalable quantum networks, *Nature* **558**, 192 (2018)

Quantum internet: A vision for the road ahead, *Science* **362**, 303 (2018)

Distributed, cloud quantum-computing,  
Entanglement-based sensing, clock synchronization,  
Quantum physics measurements  
Quantum communications, ...

Quantum information carried by single photons  
belonging to polarization entangled pairs

Optical fibers limited by absorption losses (~100 km, no-cloning),  
Free-space optics on Earth limited to line of sight (~100 km)

credit:

Quantum secure key rate and key length for one pass and for conservative instrument and link parameters:

## Atmospheric link budget

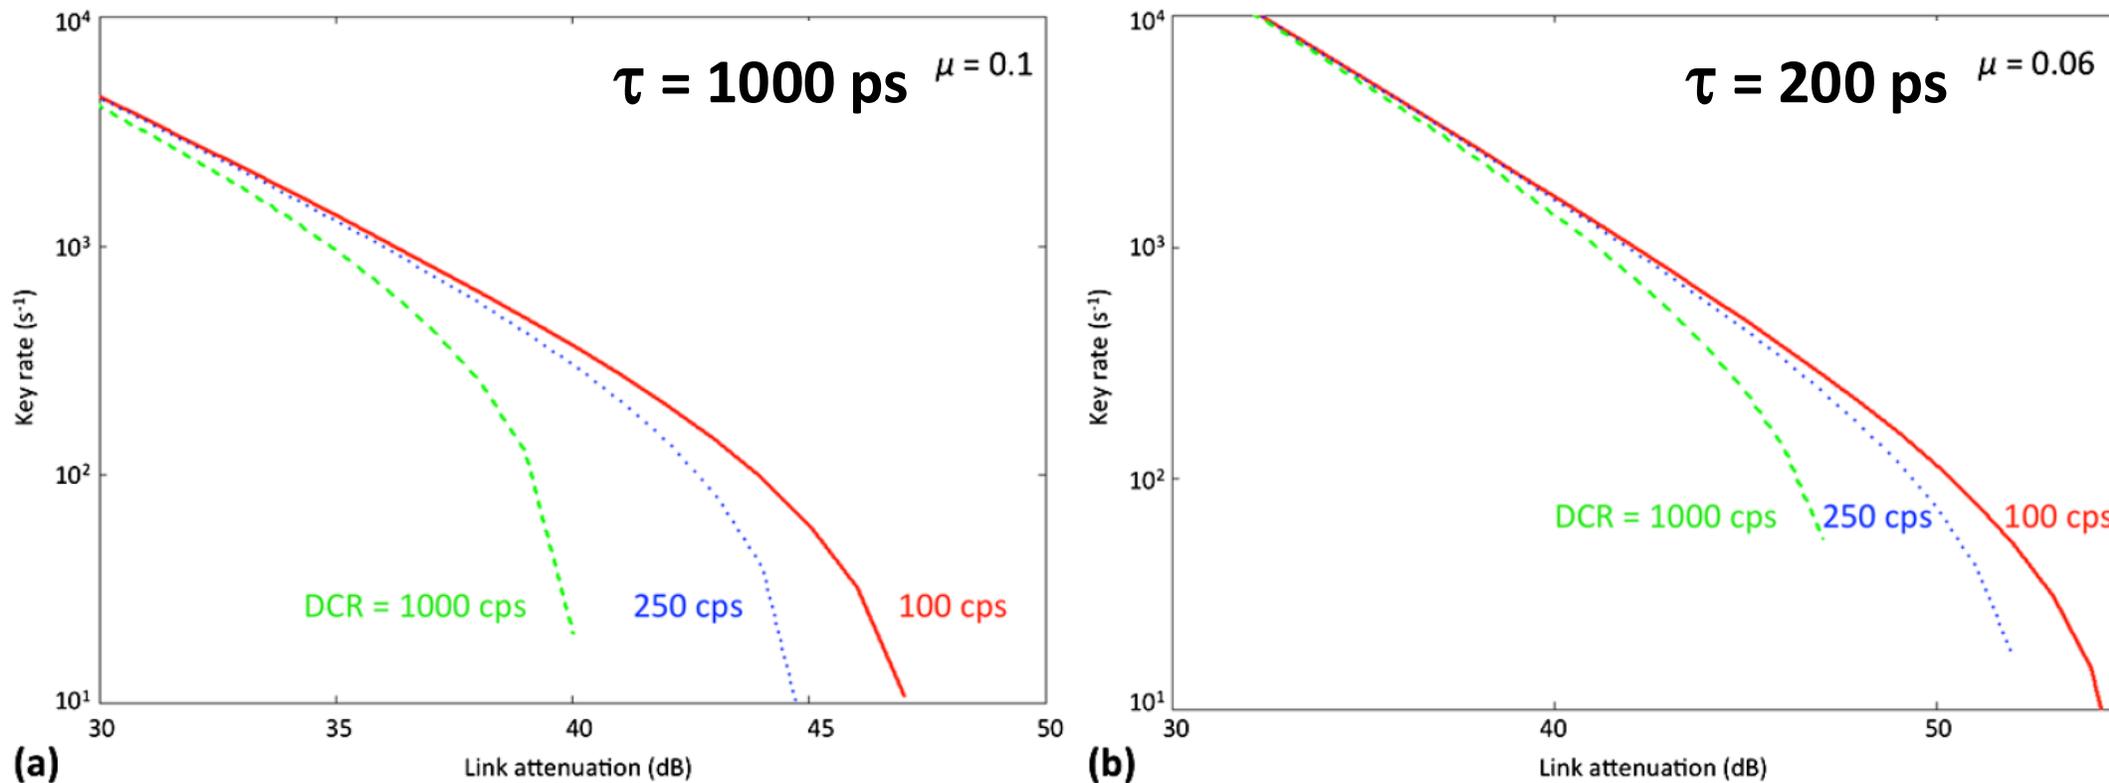

→ key length per successful pass:  $10^5 - 10^6$  bits

## Detection module & cooling

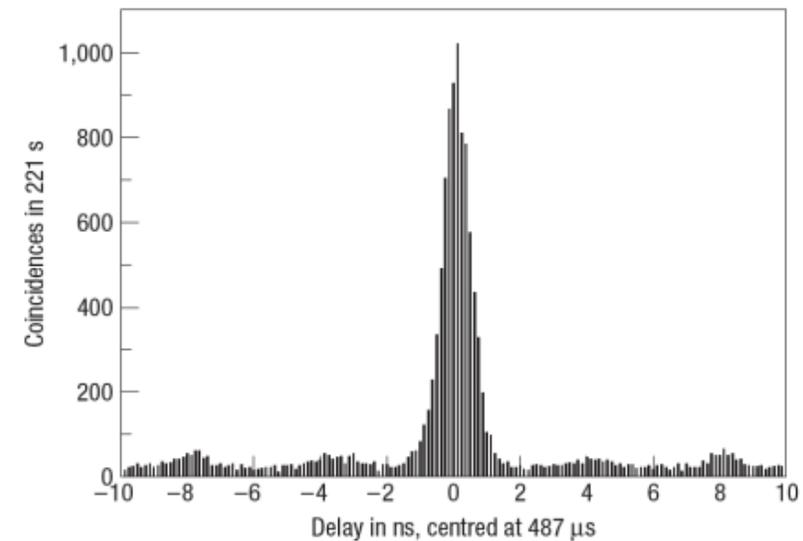

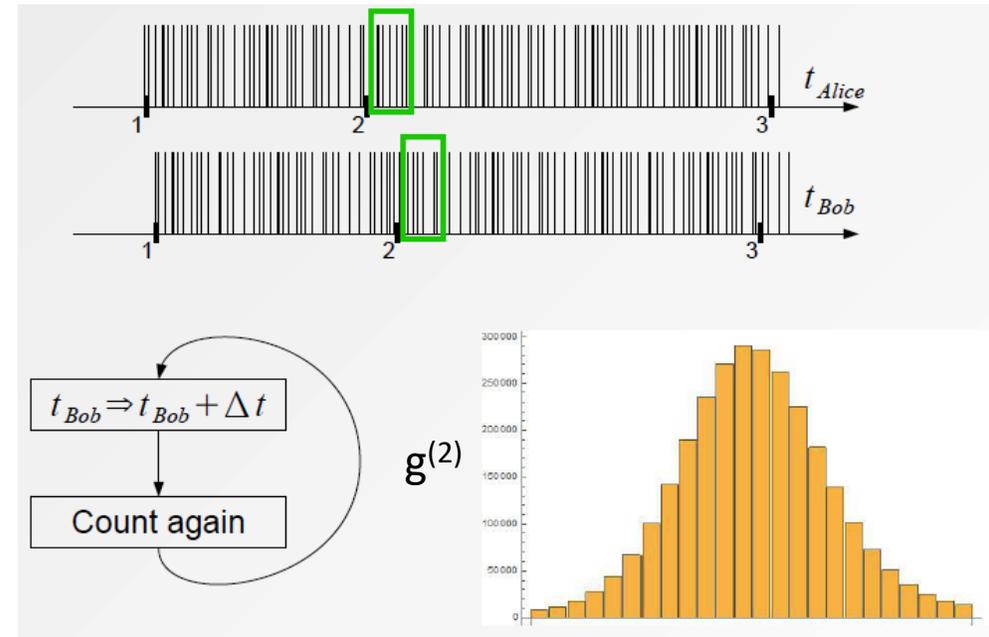

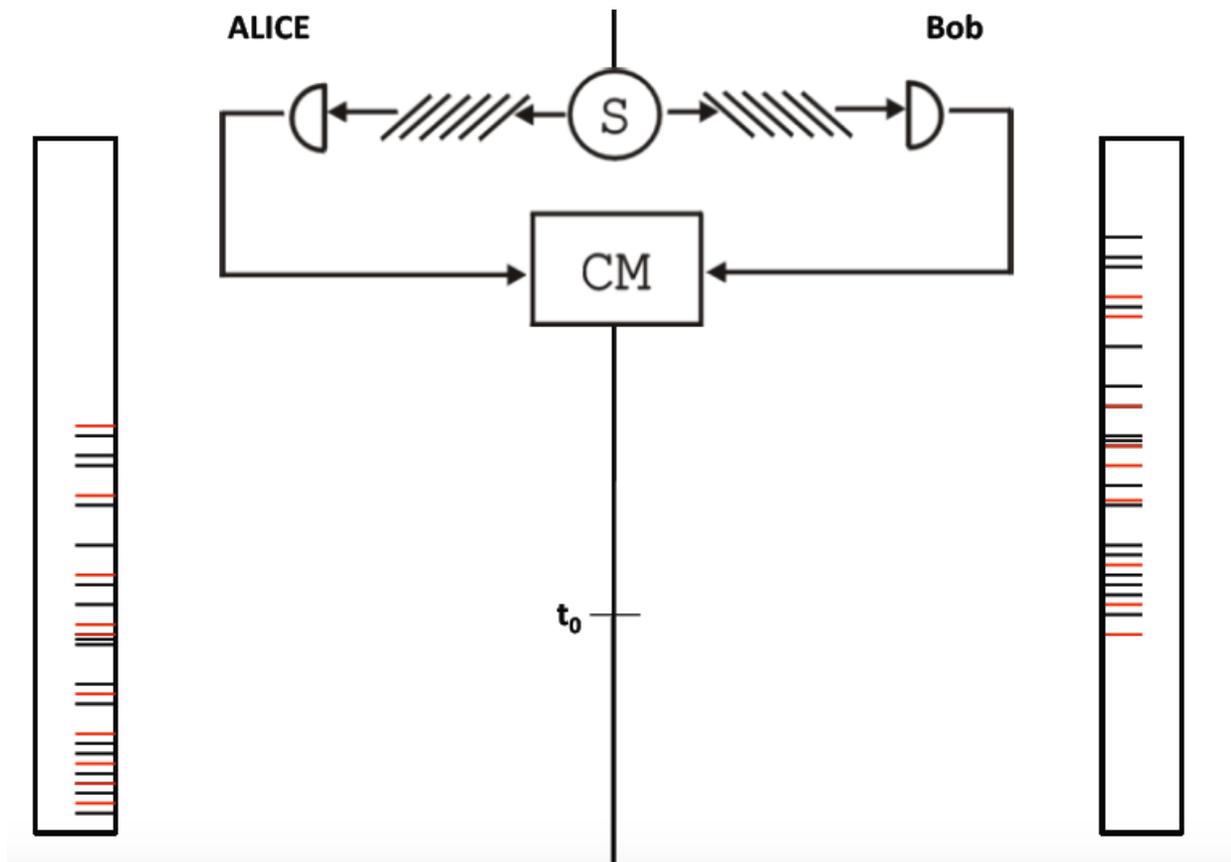

# Key rate versus coincidence time window: discrimination against dark- and background photon counts

**Figure 10** The secure secret key rate for three different values of the dark count rate as a function of the link attenuation (solid curve: 100 cps; dotted curve: 250 cps; dashed curve: 1000 cps per detector). **(a)** For the conservative parameters of Table 3 and  $\tau = 1 \text{ ns}$  and  $\mu = 0.1$  ( $R_{\text{pair}} = 10^8 \text{ s}^{-1}$ ), **(b)** same, except for  $\tau = 200 \text{ ps}$  and  $\mu = 0.06$  ( $R_{\text{pair}} = 3 \cdot 10^8 \text{ s}^{-1}$ )

# csug IQI Clock synchronisation

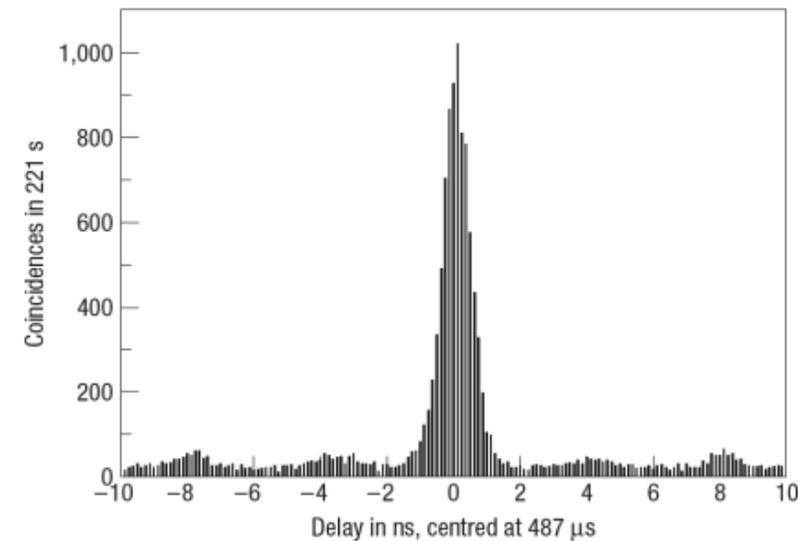

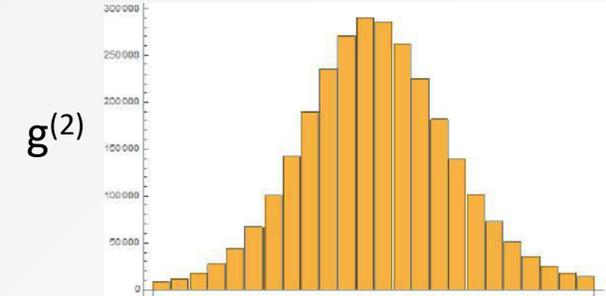

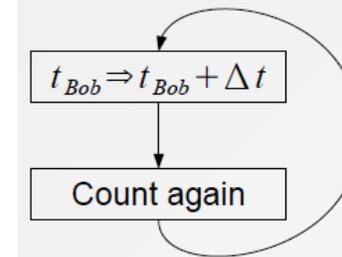

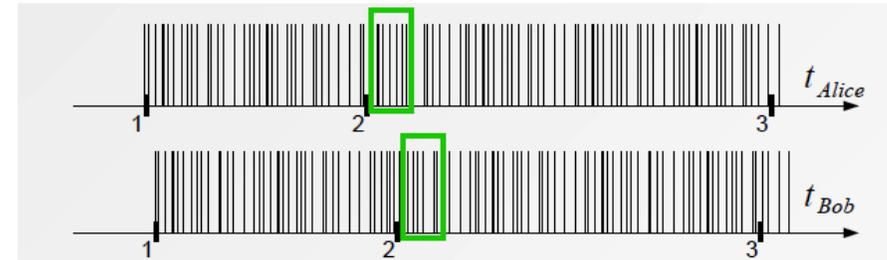

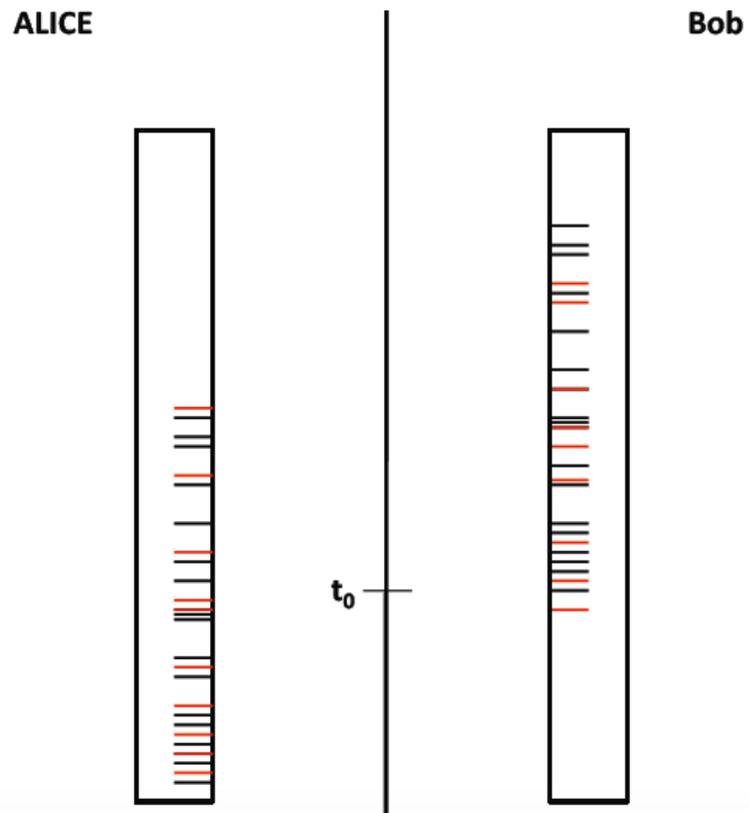

Timing of photon arrivals used to discriminate between entangled pair photons and background or dark counts.  
But how to correct for clock drift?

# csug IQI Clock synchronisation

Timing of photon arrivals used to discriminate between entangled pair photons and background or dark counts.

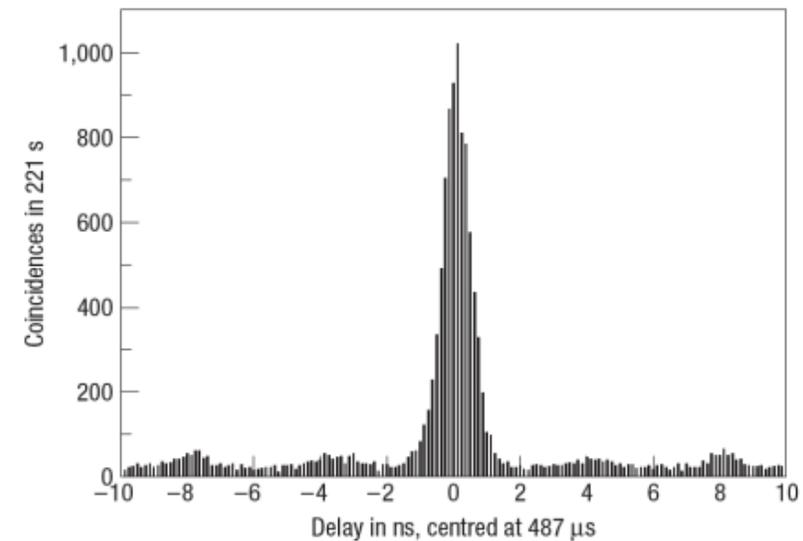

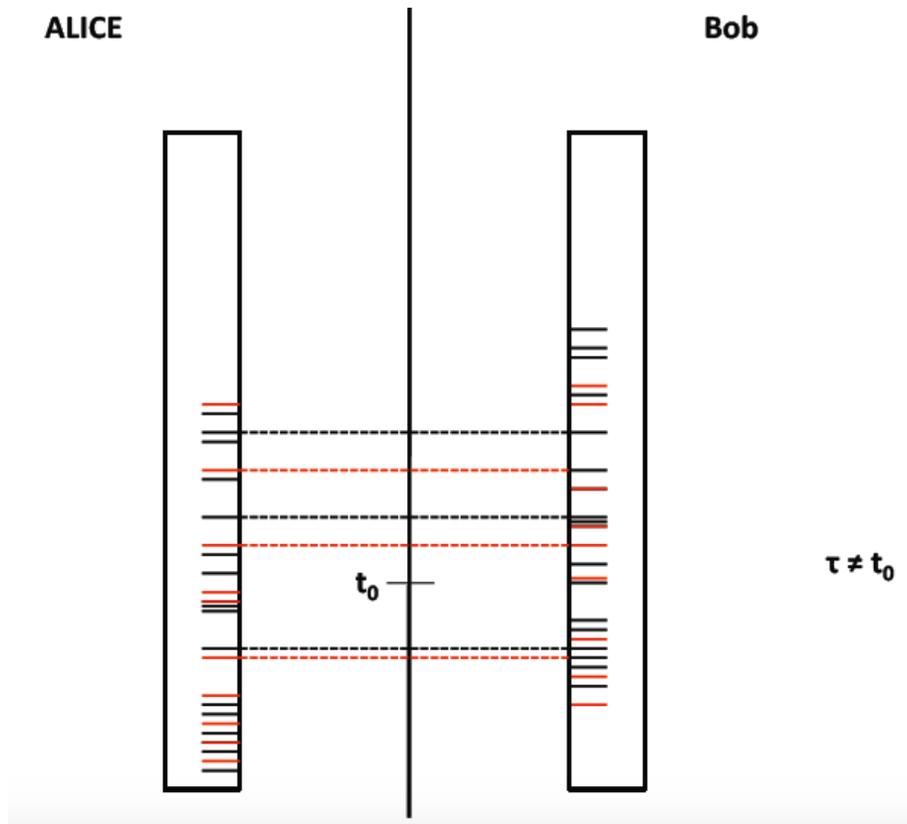

Maximize photon correlation to determine clock offset.

# CSUG IQI Clock synchronisation

Timing of photon arrivals used to discriminate between entangled pair photons and background or dark counts.

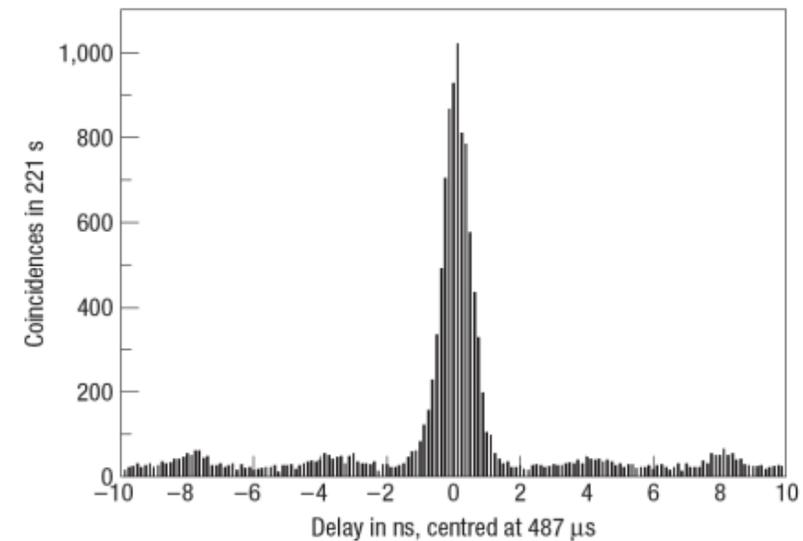

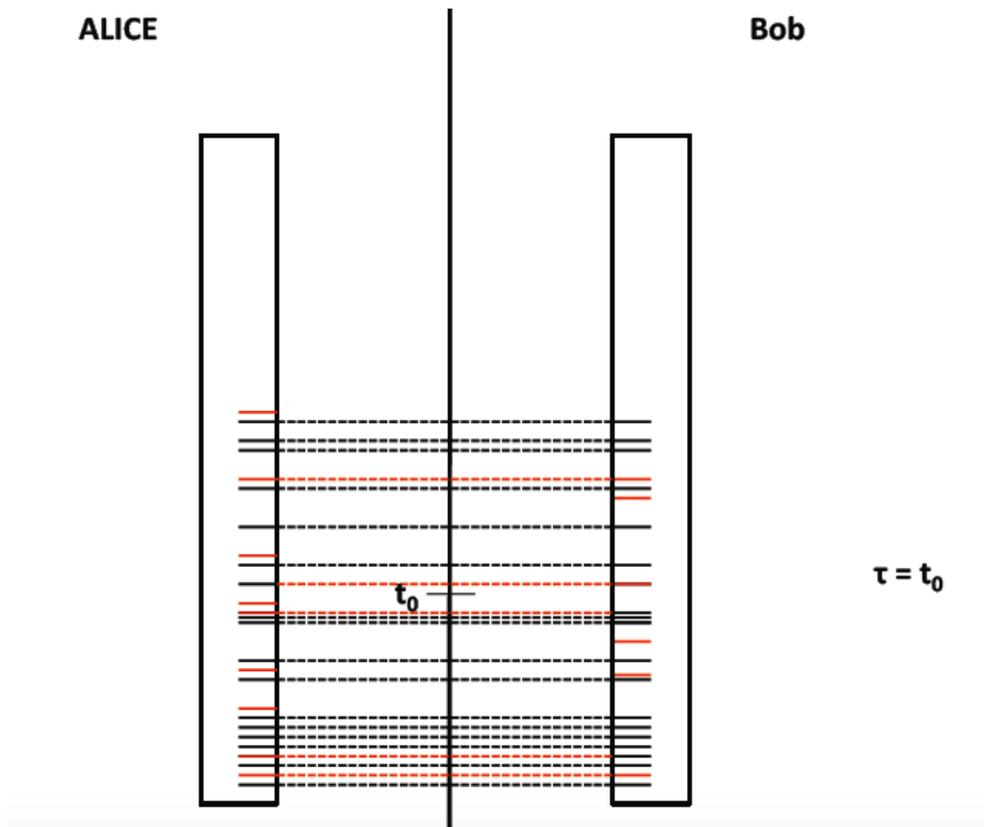

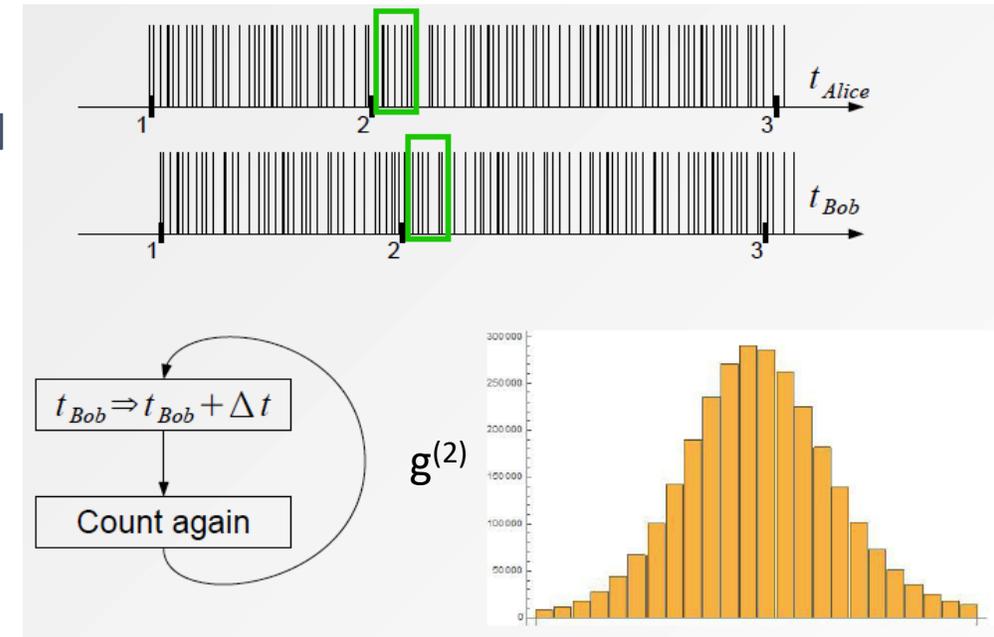

Maximize photon correlation to determine clock offset.

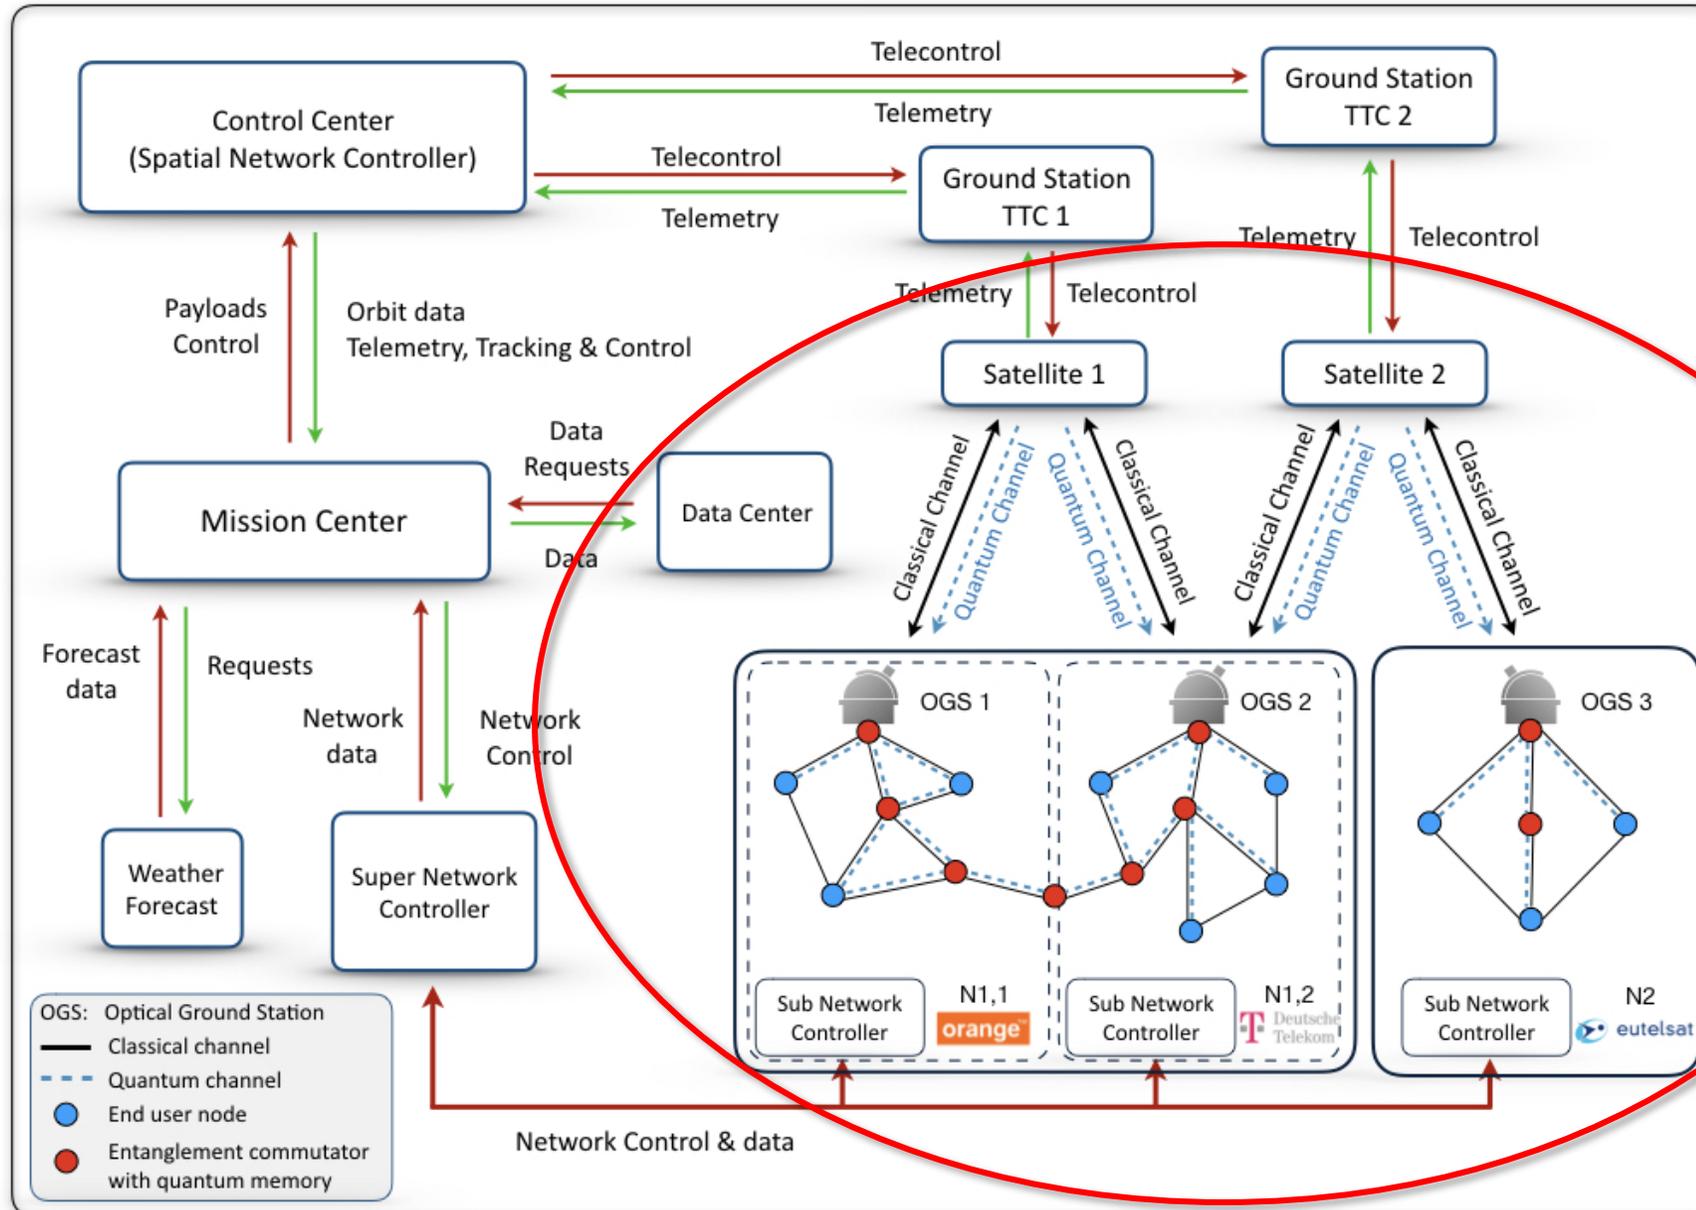

# csug IQI Clock synchronisation

Timing of photon arrivals used to discriminate between entangled pair photons and background or dark counts.

Maximize photon correlation to determine clock offset.

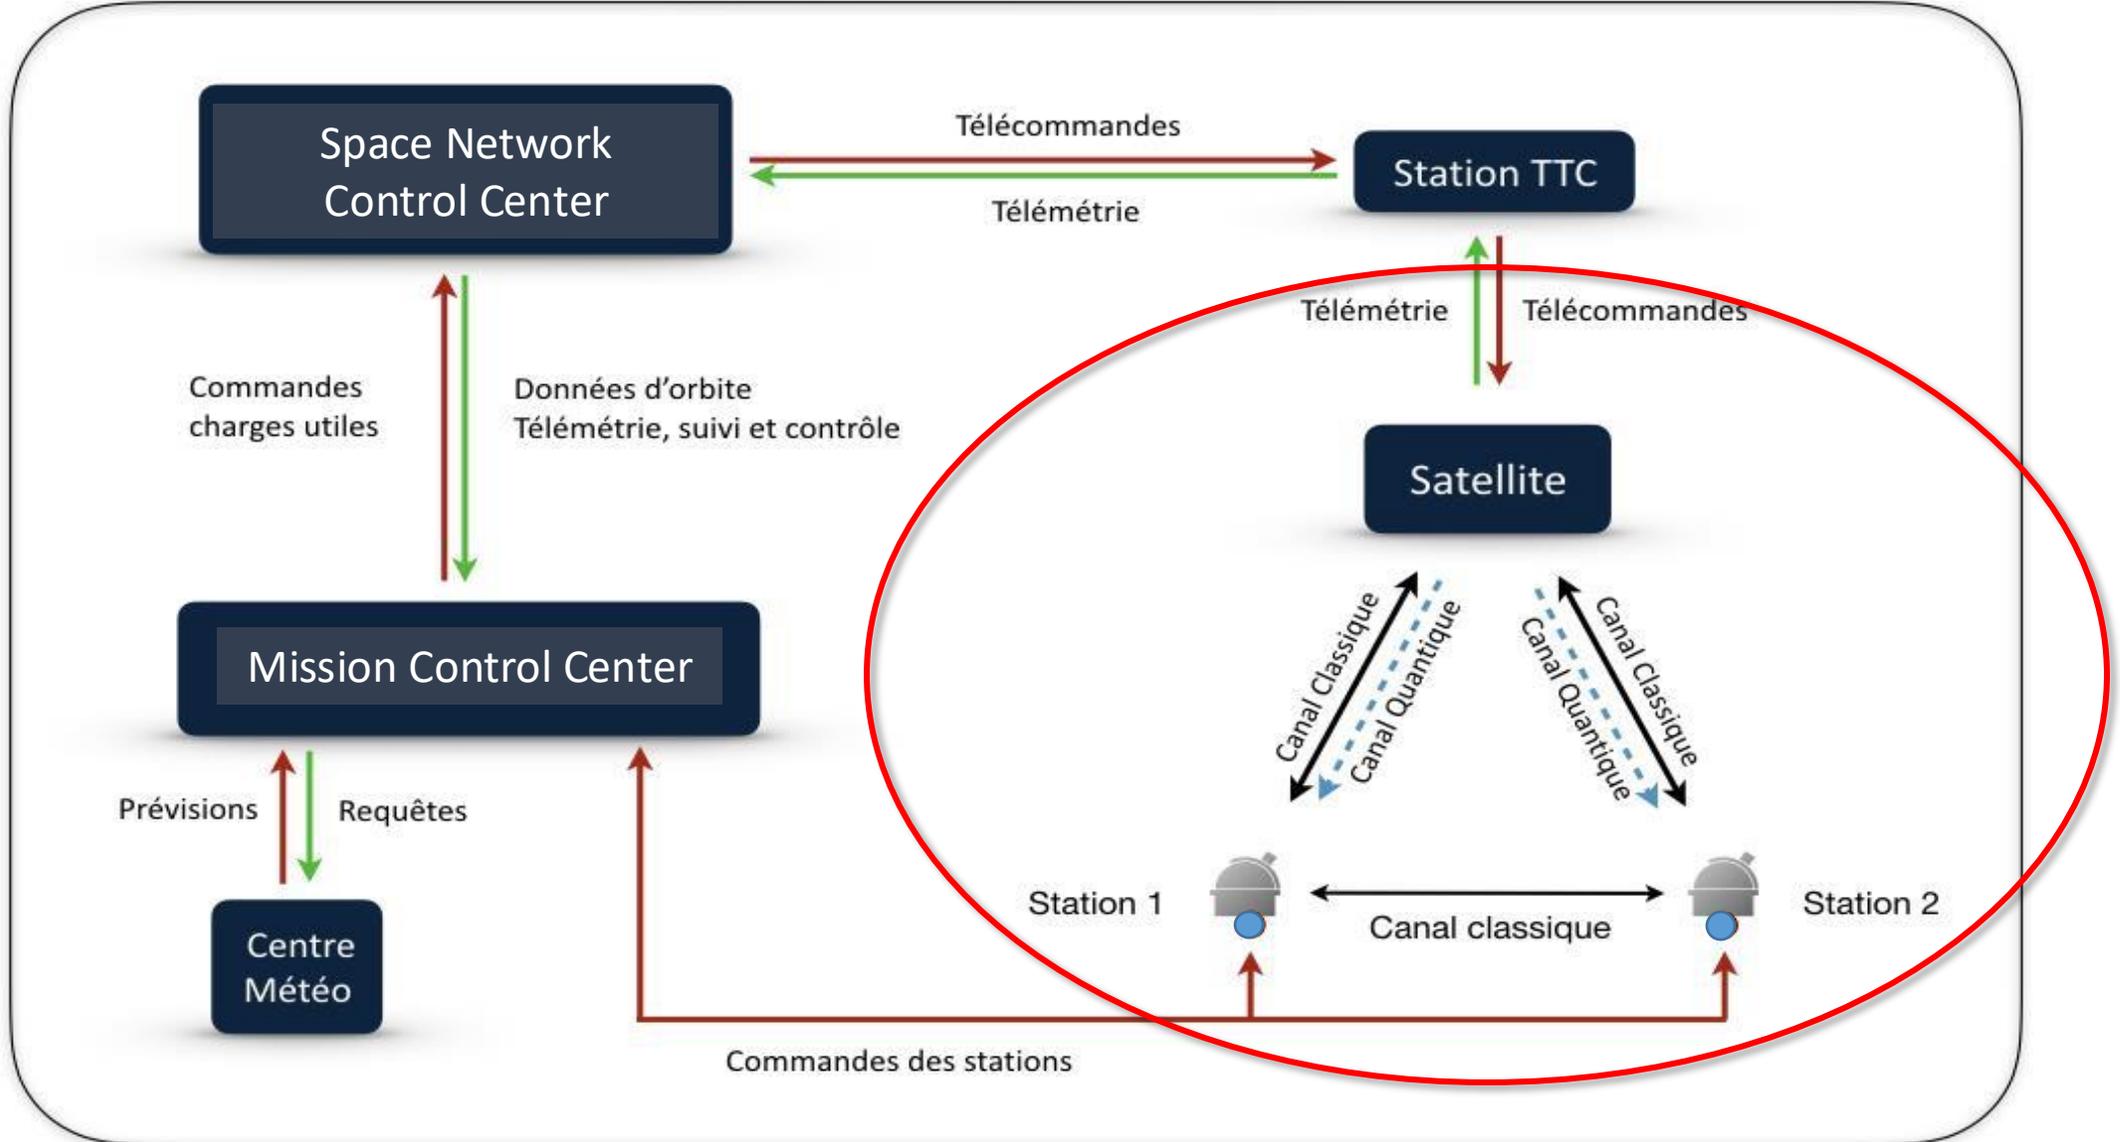

# G-QIN: Satellites distribute entangled photon pairs

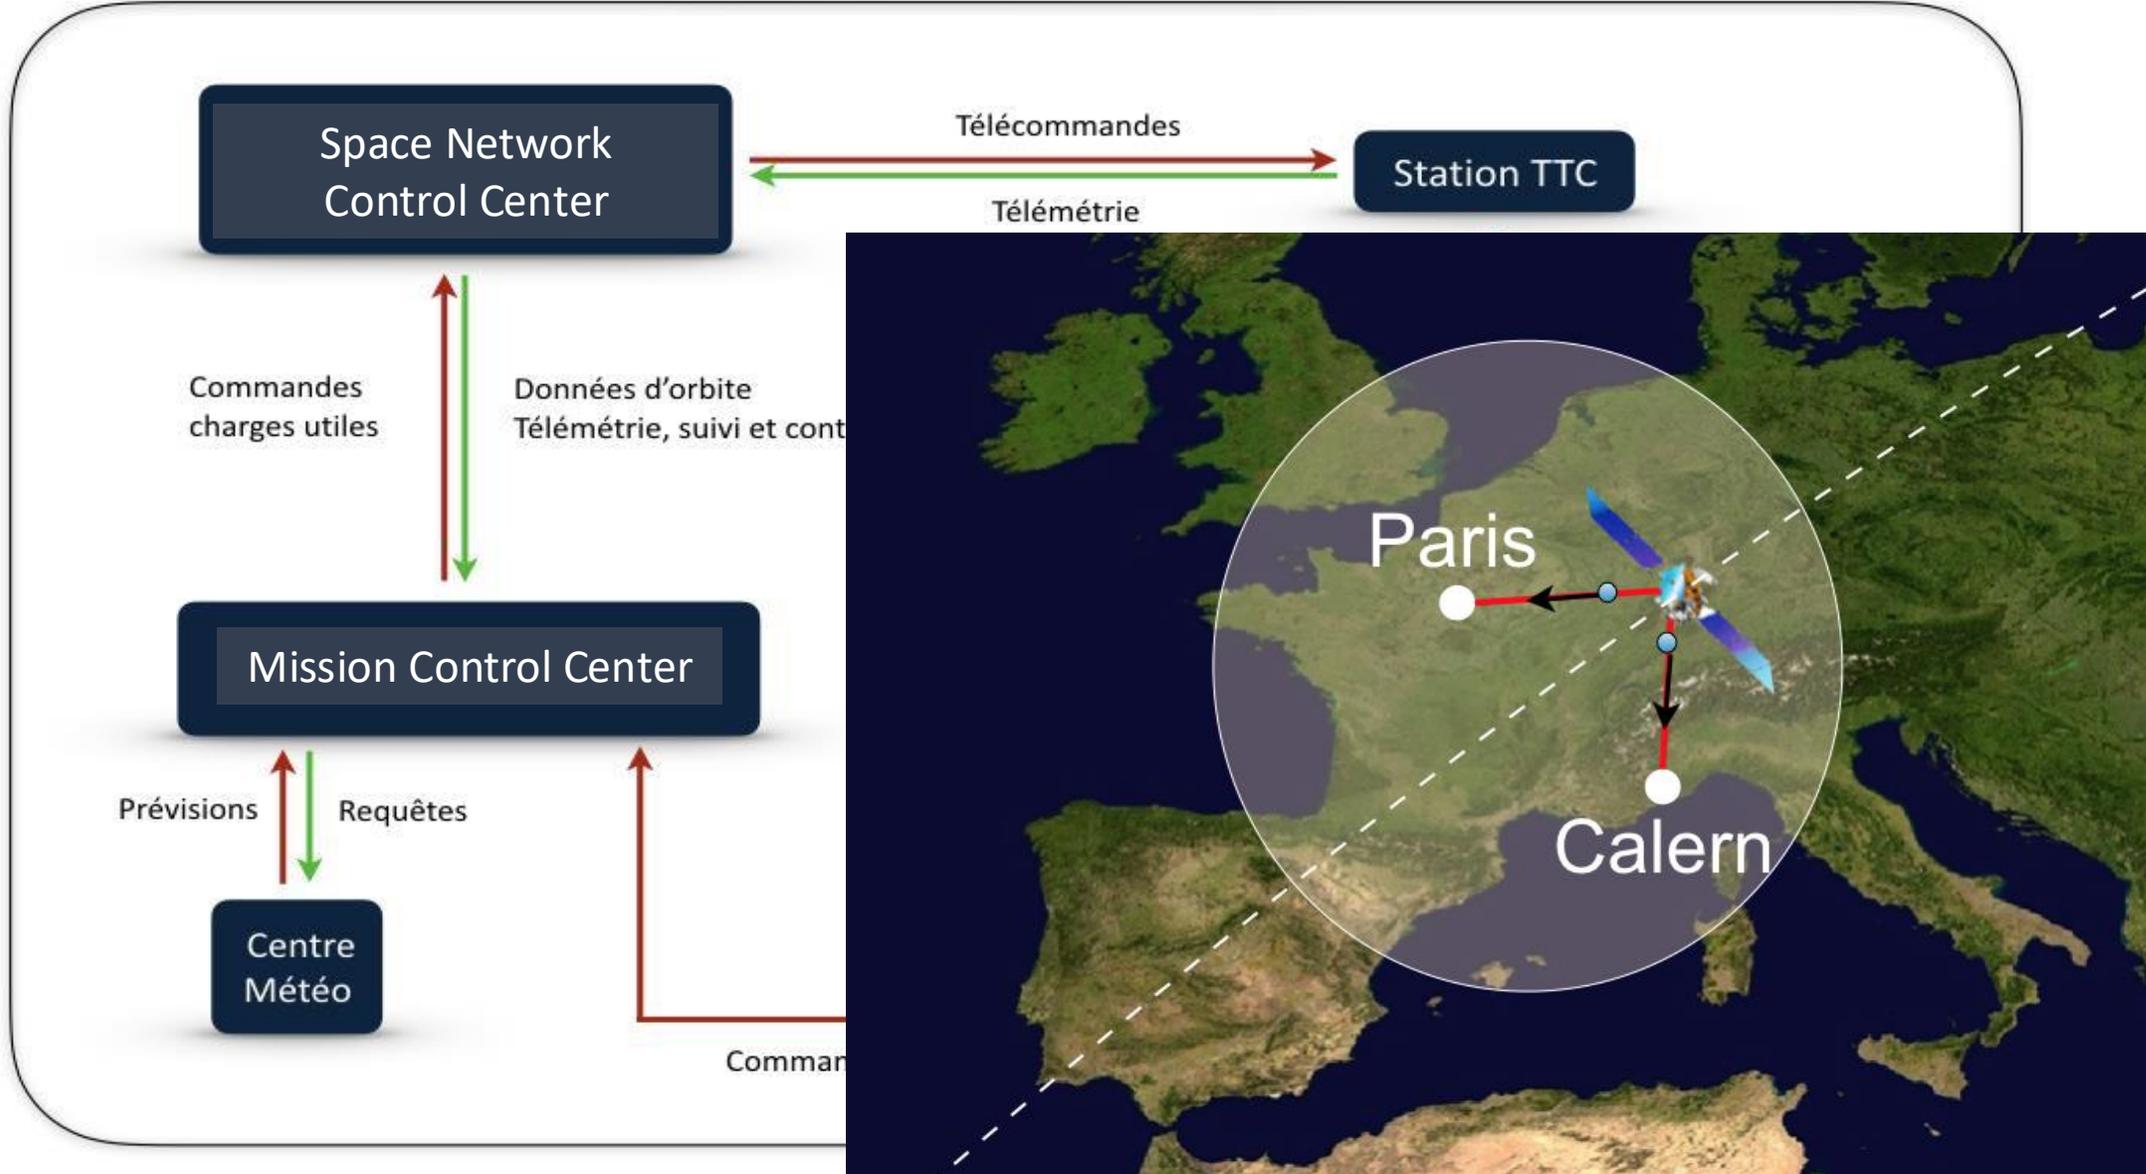

Note that an on-demand network still requires quantum memories (●)

## Simulation input parameters:

$h$	Satellite altitude (LEO / MEO)	600 / 7625	km
$q$	basis reconciliation factor	0.5	
$f(E)$	bidirectional error correction function	1.22	
$\tau$	coincidence time window	200	ps
$\mu$	average number of photon pairs per pulse	0.02	
$D_R$	OGS telescope diameter (LEO / MEO)	80 / 100	cm
$D_T$	Sat telescope diameter (LEO / MEO)	30 / 50	cm
$D$	OGS dark count rate per detector	100	cps
$B$	OGS background count rate (810 / 1550 nm)	400 / 100	cps
$N_{det}$	number of detectors	4	
$PDE$	Photon Detection Efficiency (SNSPD / IGA-APD / Si-APD)	0.9 / 0.25 / 0.68	
$\eta_{1,2}$	$\eta_{1,2} = T_{opt} \cdot T_R \cdot T_T \cdot (1 - L_p) \cdot PDE \cdot 10^{-A_{1,2}/10}$ , with $A_{1,2}$ the quantum channel 1,2 atmospheric link attenuation in dB		
$A_{atm,0}$	Atmospheric attenuation at zenith (810 / 1550 nm)	3 / 2	dB
$L_p$	Telescope pointing error (810 / 1550 nm)	0.3 / 0.2	
$T_R, T_T$	Telescope transmission factors	0.8	
$T_{opt}$	Combined optics efficiency (OGS & Sat) (810 / 1550 nm)	0.2 / 0.35	
$e_0$	error probability of dark- and background counts	0.5	
$e_d$	error probability of photon arriving on wrong detector (polarization error)	0.01	

Entangled photon source models by Ma, Fung, and Lo (2007), Neumann et al. (2021)

# « RISQ » Simulations: some results

- ▶ Realistic orbital modeling
- ▶ Long-term simulations (1 yr)
- ▶ QKD metrics as proxy for entanglement distribution efficiency
- ▶ Timing requirements for a dual link are technically feasible: **200 ps timing jitter** quite acceptable: small losses due to distillation (= discrimination against dark- and background counts + classical error correction, using arrival timing to identify entangled photon pairs).

# « RIQS » Simulation results

Conclusions:

If cost plays no role:

**SNSPDs at both wavelengths**

If cost/complexity/cooling is a concern:

**Si-APDs at 810 nm**

Note: No daylight communication at 810 nm:

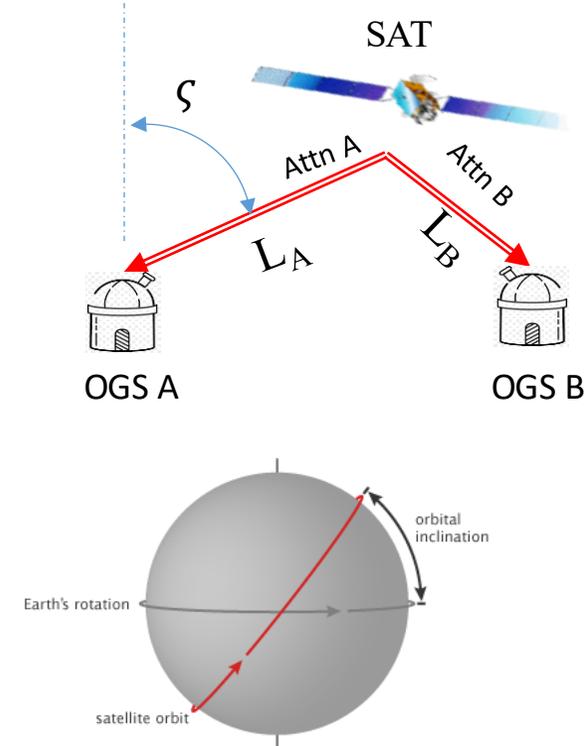

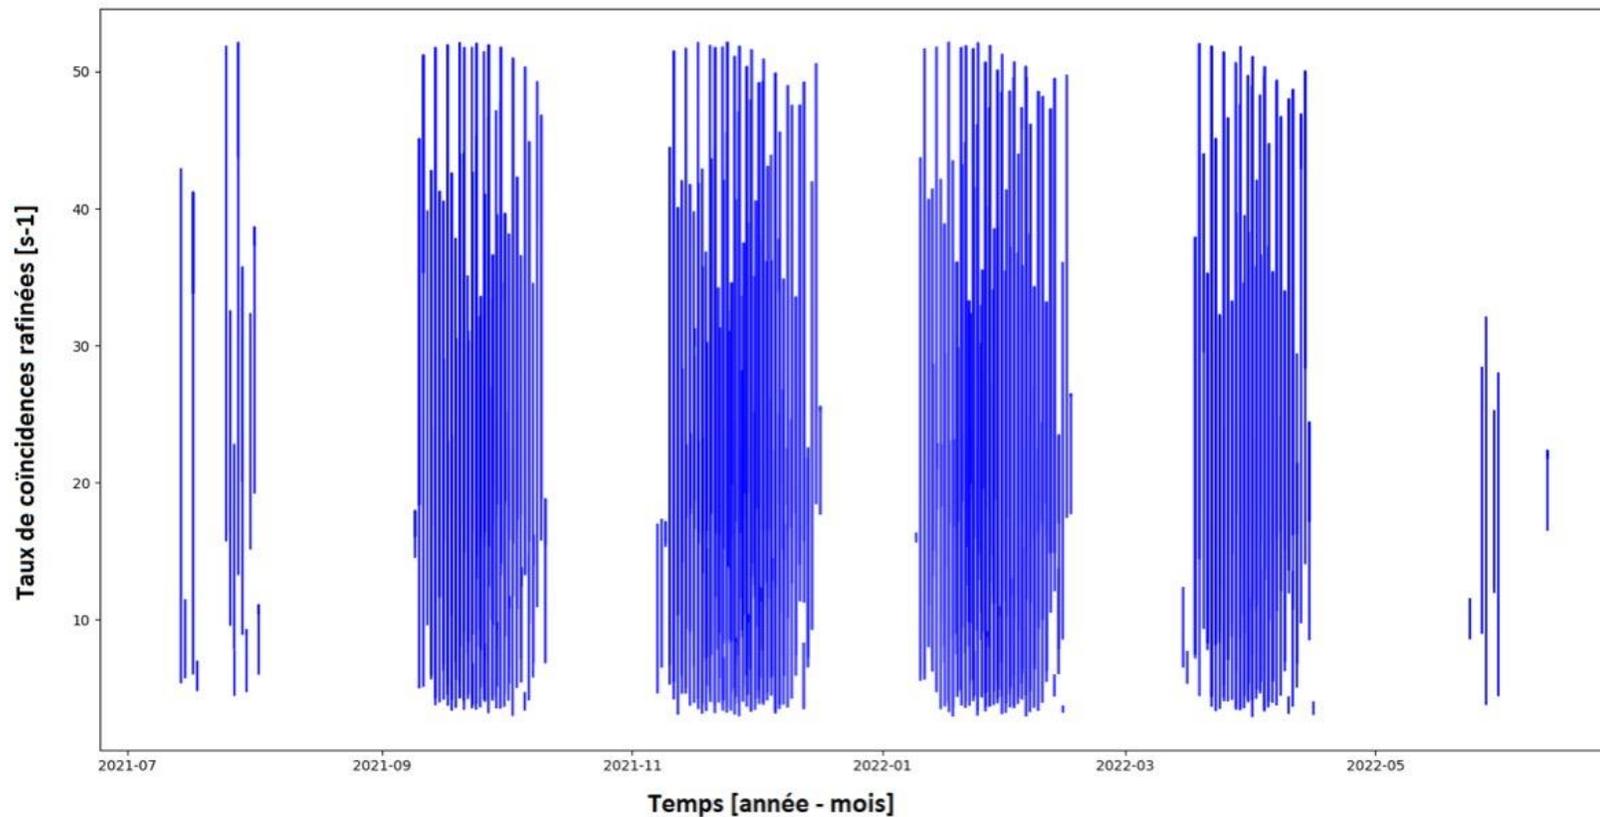

Average comm time 9.3 min/day at 1550 nm, versus 2.3 min/day at 810 nm

**LEO orbital is always to be preferred**

Average raw coincidences per day

# Highest SKR for LEO at 50° inclin.

But ... if communication is possible only during nighttime (810 nm) :

**Dual link**  
**Paris-Calern:**  
Night-time only
